# Aim of study

- ▶ Simple correlation between the compression index and relevant geotechnical index parameters
- ▶ High Plasticity Palaeogene clays

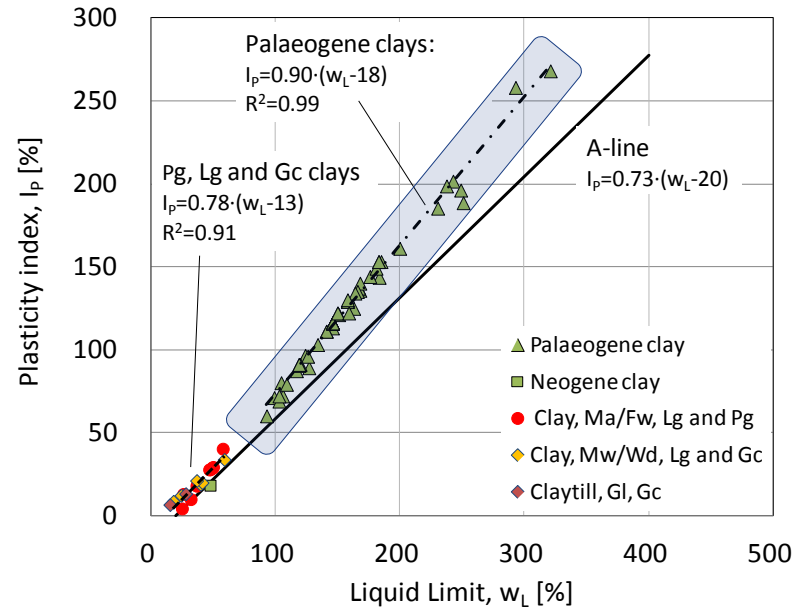

# Application

- ▶ Rough estimate
- ▶ Assessment of preconsolidation pressure
- ▶ Simulation of geological loading history

# Test details and classification of tested clays

- ▶ Very high to extremely high plasticity  $w_L > 90\%$
- ▶ Heavily overconsolidated (OCR typically  $> 10$ )
- ▶ Database of 62 1D comp. tests
- ▶ Undisturbed natural samples

Classification chart for tested Palaeogene clays

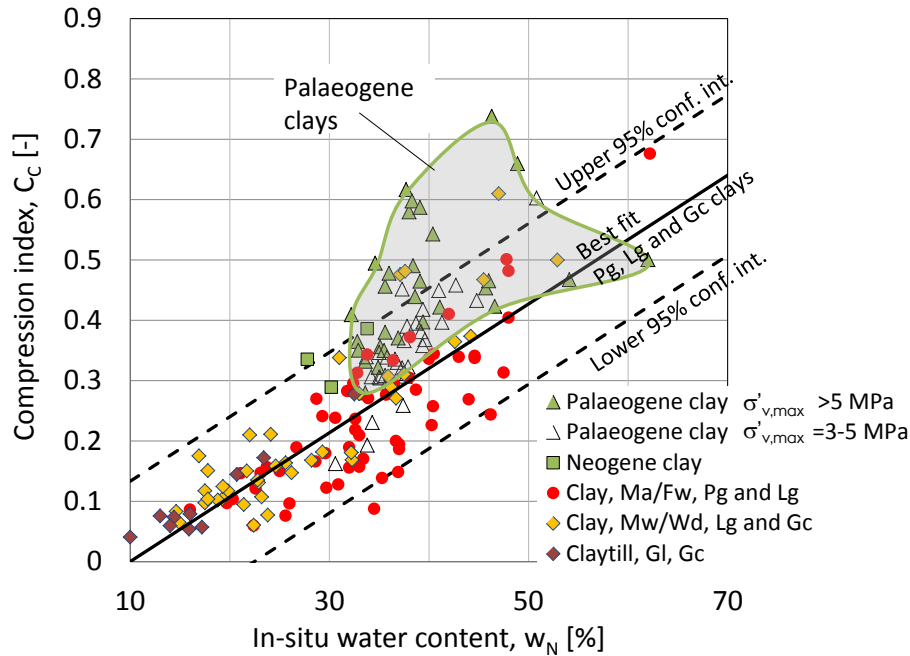

# 1D compression behaviour

- ▶ High compressibility and swelling potential.
- ▶ Fully reversible unloading-reloading curve.
- ▶ Gradual yield,  $\sigma'_{pc}$  is not easily identified.
- ▶ The compression behaviour post yield is influenced by inherent properties and structure.

Typical CRS compression curve - extremely high plasticity Palaeogene clay ( $I_p > 150\%$ )

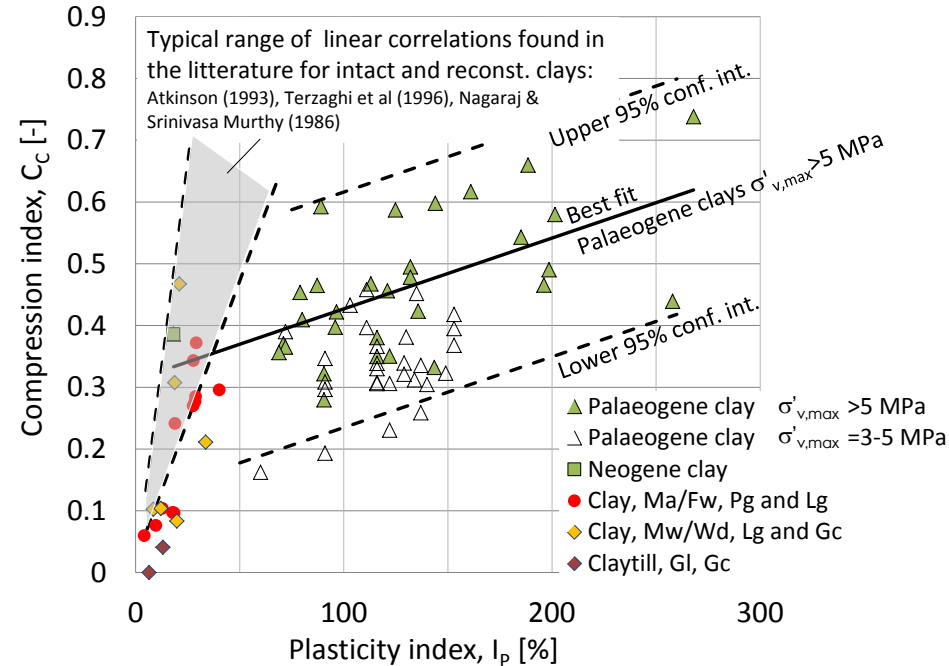

# Compression index $C_c$ vs. natural water content, $w_N$

- ▶ Large scatter.
- ▶ Tendency of increasing  $C_c$  with increasing  $w_N$ .
- ▶  $C_c$  correlate well with  $w_N$  for Quaternary clays (ref. Andersen 2012)
- ▶  $C_c$  for Palaeogene clays appears to be influenced by OCR

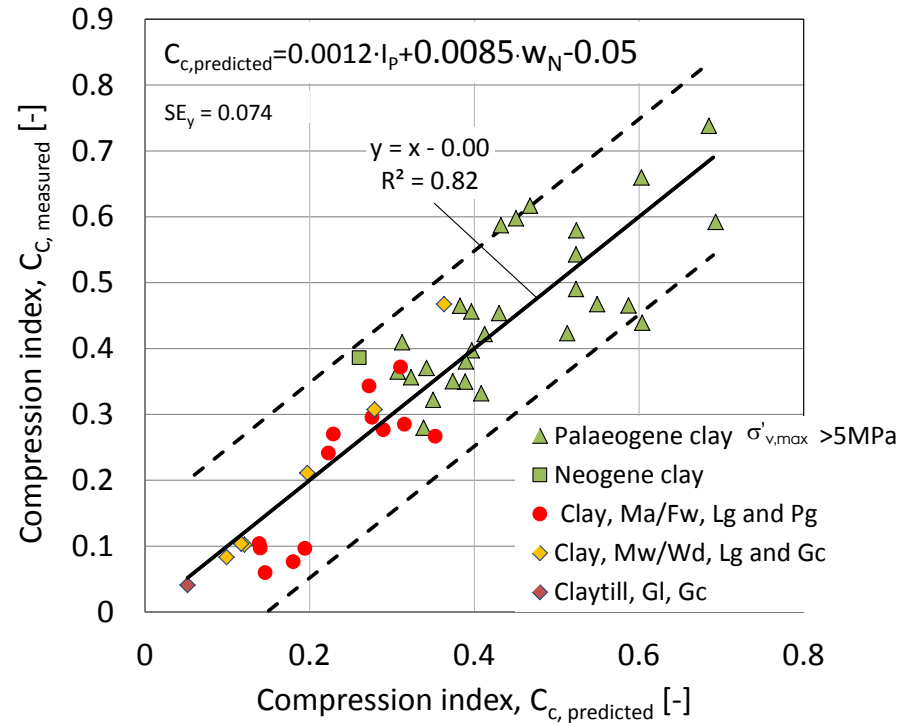

# Compression index $C_c$ vs. Plasticity index, $I_p$

- ▶  $C_c$  seen to increase with increasing  $I_p$ .
- ▶ Large scatter.
- ▶ Extremely high plasticity clays show deviating behaviour
- ▶ Correlations found in the literature are generally not applicable for  $I_p > 70\%$ !
- ▶ Virgin state may not have been reached in some cases ( $\sigma'_{v,max} < 5$  MPa)

# A “unified” correlation is propose

- ▶ Compression index a linear function of both natural water content and plasticity index (or liquid limit)
- ▶ Applicable to both Palaeogene clays and Quarternary clays - reasonable fit
- ▶ However, still large scatter!

Measured vs. predicted compression index

# Considerations

- ▶ Further improvements may be possible!
  - › Specific soil types
  - › Index parameters from test specimen
  - › Combinations of other variables
- ▶ Correlations based on  $w_L$  (cf. paper) may be preferred over  $I_p$
- ▶ A unique correlation does not exist!
  - › Influence of structure, mineralogy, clay size fraction, state, pore water chemistry etc.
