First version: June 2008

This version: May 2009

Abstract

In this paper, we use a detailed dataset containing information about all international trade transactions of the population of Danish firms over more than a decade to analyze the relationship between export and import decisions and employment growth. We further distinguish between imports of final goods and imports of intermediate products. We find that both imports and exports decisions are positively related to employment growth. Interestingly, both finished goods and intermediate goods imports have a positive link. We also control for the re-exporting process, i.e. firms importing final goods to re-export them afterwards.

Keywords: international trade, employment growth, offshoring

JEL Codes: F16,

1 Introduction

International trade and outsourcing are often blamed for destroying jobs. Yet, most economists would agree that firms take their international trade

decisions in order to increase productivity. They believe that firms to which they delegate some tasks from the production process will be more efficient at executing these tasks than they would have otherwise done it themselves, so that firms can redirect their resources towards high value added activities. And more productive firms are also more likely to maintain their workforce and hire new workers.

This productivity effect is often missing from theoretical models of outsourcing. A recent theoretical paper (Grossman and Rossi-Hansberg, 2008) provides a novel framework. In their model, reduction in transportation and communication leads to a new global division of tasks between countries. Offshoring some tasks abroad is beneficial for the firm if factor costs are lower, but it can also generate some coordination problems. Firms therefore face a trade-off and take their offshoring decisions to minimize costs. An improvement in the opportunities to offshore induces three different effects: a productivity effect, a relative-price effect, and a labor-supply effect (the next section discusses these issues in details). The authors stress that the productivity effect should prevail in a small open economy. This paper provides an empirical test of this theory from the perspective of a small open economy.

In this paper, we use a detailed dataset containing information disaggregating all Danish firms' imports and exports decisions by product and origin/destination over more than a decade to analyze their relationship with employment growth. We further distinguish between imports of final goods and imports of intermediate products. We find that both imports and exports decisions are positively related to employment growth. Interestingly, both finished goods and intermediate goods imports have a positive link. We also control for the re-exporting process, i.e. firms importing final goods to re-export them afterwards.

We perform both a short run and a long run analysis. In the long run, a change in imports is negatively associated with employment growth only for the subsample of large firms. In addition, we look at the relationship between

international trade and employment growth by education category. We find that an increase in imports is more strongly associated with an increase in the demand for college-educated workers in the long run.

Our results contrast with those from a recent paper by Biscourp and Kramarz (2007). They find that increases in both imports of finished goods and imports of intermediate goods are associated with more job destruction in the long run analysis, although the link with the former is stronger. They also find that the relationship was stronger for large firms. The fact that our results differ so much is not necessarily *so surprising*. Indeed, France and Denmark differ in many dimensions, most notably in terms of market size, labor market institutions and product specialization. Therefore this paper provides additional light regarding a politically very sensitive topic from the perspective of a small open economy.

The paper is organized as follows. Section 2 discusses the current debate regarding outsourcing and import decisions and the existing literature. Section 3 describes our unique dataset and our empirical methodology. Section 4 shows our results. Section 5 concludes and offers some policy implications regarding the role of import decisions and outsourcing.

2 Literature

There is a common belief among economists that free trade is associated with long run welfare gains using standard Ricardian arguments. In the political debate, offshoring is often simply considered as another measure of trade. Yet, the exact mechanisms through which it endogenously affects firms' other decisions are likely to be different, and only a few theoretical models highlight these differences. A recent paper by Grossman and Rossi-Hansberg (2008)¹ fills a gap in the literature in that respect. They focus on the consequence on wages for unskilled workers, but a similar analysis can be

¹Note that their model assumes perfectly competitive markets. If offshoring enhances firms' market power, this could be another channel affecting employment and wages. See their footnote 13.

conducted on labor demand. The intuition is the following: the production process can be divided into tasks. Some tasks must be performed by high skilled workers, while some others can be performed by low skilled workers, either domestically or abroad. There are two sectors: one high-skill intensive and one low-skill intensive. Lower transportation and communication costs make offshoring easier. When foreign wages are lower than domestic wages, firms have an incentive to offshore parts of their production process, although it might lead to some coordination costs. Therefore, the equilibrium allocation of tasks depends on this trade-off and will be affected when lower transportation and communication costs make offshoring easier. Some tasks that use to be made domestically are now offshored to the foreign country. This leads to a labor cost reduction for the firm (the productivity effect), an increase in profitability and in labor demand for low skilled workers, as the low skill intensive sector expands relatively more.

Offshoring might also affect the type of labor that the firm wants to employ, and therefore the skill composition of the workforce, as the firm will focus on its core activities, those with more value added. There will be less tasks for low skilled workers to be executed domestically, what might lower the demand for low skilled workers (labor supply effect).

More generally, they show that, when new opportunities for offshoring arise (as a consequence of falling trade or communication costs), whether low-skilled² domestic workers are going to be negatively affected depends on the strength of three different effects:

- a productivity effect (the firm benefits from cost saving and this benefits the workers as well, as it raises labor demand for low-skilled),
- a relative-price effect (the new opportunities from offshoring alter the country's terms of trade; if the relative price of the labor-intensive good falls, this leads to a downward pressure on low-skill wage)

²The authors also discuss the implication for high-skilled workers. We will get back to this later on.

- a labor-supply effect (reallocated labor must be reabsorbed in the economy, what might lead to a decline in their wage).

In a small open economy such as Denmark, Belgium, or the Netherlands, the terms of trade are likely to be fixed, while wages could react to factor supplies, but we expect that the productivity effect will be the strongest force.

On the empirical side, a recent paper by Biscourp and Kramarz (2007) looked at the link between changes in firm level trade and employment growth. They find that increases in both imports of finished goods and imports of intermediate goods are associated with more job destruction, although the link with the former is stronger. They also find that the relationship was stronger for large firms.

A few recent papers use a similar Danish dataset to analyze the effect of international trade on workers' well being. Rosholm et al. (2007) look at relative skill composition and international trade; Munch and Skaksen (2005) look at the impact of outsourcing on wages; and Munch and Skaksen (2008) looks at the link between export status and wages.

3 Data

We use several data sources provided by Statistics Denmark. Our main dataset is the *Foreign Trade Statistics* (Udenrigshandelsstatistikken)³, a dataset that includes both values and quantities⁴ of import and export of goods at the firm level by product (8 digit CN, combined nomenclature) and origin, or destination. The data is available for the period 1993-2003. Table 1 shows some summary statistics. We see that the number of firms involved in in-

³See http://www.dst.dk/HomeUK/Statistics/focus_on/focus_on_show.aspx?sci=1202 for more information on the dataset. See also Pedersen (2008) and Eriksson, Smeets and Warzynski (2008) for detailed summary statistics.

⁴In this paper, we only use the information about the value of the transaction. See Warzynski (2008) for an analysis of price behavior.

ternational trade has decreased over time , while the number of transactions and the average value has increased.

We merge this dataset with the *Firm Statistics* dataset that adds information about turnover, material costs, number of full time employees, industry at the firm level and type of firm (private, public) for the population of Danish firms. Table 2 shows the number of firms according to different size thresholds. We can clearly observe a data break in 2000. Indeed, until 1999, only firms subject to VAT and from the private sector were sampled, while all firms are covered from 2000 onwards. On the other hand, Statistics Denmark also cleaned the dataset by including only firms that were actually active, while it included all registered entities previously.

For robustness reasons, we also use the *Accounting Statistics* dataset (Regnskab) that contains information on less firms, for a shorter period (1995-2003), but provides more accounting variables. In particular, it provides information on the capital stock in the firm, so that we can control for differences in capital-output ratio.

Finally, we use the IDA database, a longitudinal database that contains information about all individuals aged 15 to 74 (demographic characteristics, education, labor market experience, tenure and earnings) and employees in all workplaces in Denmark during the period 1980-2005 and information on all workplaces (industry, geographical placement, changes in status, type of firm) in the same period. This information has been collected by merging information from several registers in Statistics Denmark with the help of unique identification numbers for individuals and workplaces. Persons and workplaces are matched at the end of November each year. We mostly need the information from IDA to look at workforce composition by type of education.

4 Empirical Methodology

Our methodology differs from Biscourp and Kramarz (2007) in a few dimensions. We discuss also how our results are likely to be affected by these differences and test the robustness of our findings.

First, we create a year-by-year employment growth variable following Davis and Haltiwanger (1990, 1992):

$$\Delta n_{it} = \frac{(N_{it} - N_{it-1})}{\frac{(N_{it} + N_{it-1})}{2}}$$

This measure of firm growth is bounded between -2 (exit) and 2 (entry). As explanatory variables, we include the growth of output as a measure of economic shock. We also include firm size and firm size squared. We are mostly interested in the relationship between employment growth and change in international trade at the firm level. We compute a few measures: the change in export intensity and the change in import over sales. We further divide imports into imports of finished products (defined as products from the same 2-digit industry) and imports of intermediary products (defined as products from different industries)

Therefore the regression that we estimate is the following:

$$\begin{aligned} \Delta n_{it} = & c + \alpha_1 \Delta \log(\text{Sales})_{it} + \alpha_2 \Delta(\text{FG Imports/Sales})_{it} & (1) \\ & + \alpha_3 \Delta(\text{II Imports/Sales})_{it} + \alpha_4 \Delta(\text{Exports/Sales})_{it} \\ & + \alpha_5 \log(\text{Size})_{it-1} + \alpha_6 [\log(\text{Size})_{it-1}]^2 \\ & + \text{YearDummies} + \text{IndustryDummies} + \varepsilon_{it} \end{aligned}$$

We also tested various alternative specifications: using firm age as additional controls; using the capital output ratio. We also run the regressions separately for the manufacturing and service industry. We also look at the sensitivity of the measured relationships by size category.

To compare our analysis with Biscourp and Kramarz (2007), we also run a long run regression. We compute the long run employment growth the

following way by first defining employment at the beginning of the period and at the end:

$$N_i^B = \frac{N_i^{93} + N_i^{94}}{2}, \quad N_i^E = \frac{N_i^{02} + N_i^{03}}{2}$$

and then by looking at the growth rate between the two periods:

$$\Delta n_i^{LR} = \frac{N_i^E - N_i^B}{\frac{N_i^E + N_i^B}{2}}$$

We then run a similar analysis than before, where all our right hand side variables are expressed over the long run as well. It should be obvious that, by using this methodology, we only consider surviving firms and that we end up with one observation by firm, therefore limiting the dynamics.

Our second test tries to distinguish between skilled (N^S) and unskilled labor (N^U):

$$\begin{aligned} \Delta n_i^{LR,S} = & c + \alpha_1 \Delta \log(Sales)_i + \alpha_2 \Delta(FG \text{ Imports}/Sales)_i \quad (2) \\ & + \alpha_3 \Delta(II \text{ Imports}/Sales)_i + \alpha_4 \Delta(Exports/Sales)_i \\ & + \alpha_5 \log(\text{Size})_{iB} + \alpha_6 [\log(\text{Size})_{iB}]^2 \\ & + YearDummies + IndustryDummies + \varepsilon_{it} \end{aligned}$$

$$\begin{aligned} \Delta n_i^{LR,U} = & c + \alpha_1 \Delta \log(Sales)_i + \alpha_2 \Delta(FG \text{ Imports}/Sales)_i \quad (3) \\ & + \alpha_3 \Delta(II \text{ Imports}/Sales)_i + \alpha_4 \Delta(Exports/Sales)_i \\ & + \alpha_5 \log(\text{Size})_{iB} + \alpha_6 [\log(\text{Size})_{iB}]^2 \\ & + YearDummies + IndustryDummies + \varepsilon_{it} \end{aligned}$$

5 Results

5.1 Short Run Analysis

Table 3 shows the OLS results from the estimation of Eq. (1), as we are mostly interested in looking at the correlation, not the causality. Results are almost not affected when we add industry dummies, but the coefficients change quite dramatically when we include a fixed effect, especially for the effect of firm size. The coefficient of the change in export intensity is always positive and significant, while the link between the change in import share and employment growth is positive in some specifications, sometimes not significant, but never negative. The effect is generally stronger for finished goods than for intermediate goods in manufacturing. This can be interpreted as a consequence of the productivity effect stressed in the model, or as a selection effect. Those firms that became more involved in international activities are also the ones that increased employment. Table 4 controls for the re-exporting possibility by distinguishing between exports from the same industry and exports from a different industry.

5.2 Long Run Analysis

Table 5 shows the results of the long run analysis. We can see again that both imports and exports are positively related to firm growth, but the effect of imports is not significant for firms with more than 10 employees. However, in table 6, when we look at a more selected sample of firms larger than 50 employees (at the beginning and at the end of the period), the results change dramatically, suggesting that employment decisions of large firms were more sensitive to international trade behavior, as suggested by Biscourp and Kramarz (2007).

5.3 Workforce Composition

As a next step, we also look at the relationship between firm level trade and workforce composition. We want to see whether the growth of import is related to the change in the share of college educated people in the firm. We only look at the long run relationship for the subsample of large firms⁵. Table 7 and 8 show that an increase in the share of college educated workers was more likely in firms where imports grew, while an increase in the share of workers with basic education was more likely when exports were growing.

6 Conclusion

In this paper, we looked at the relationship between employment growth and the growth of trade at the firm level. Contrary to a previous study from France, we found that the growth of imports in the short run analysis had a positive effect in most specifications. In the long run analysis, a change in import share had a negative effect on employment growth only for the subsample of large firms. This suggests that firms' international trade decisions might facilitate the growth of small and medium firms, while at the same time triggering a substitution effect for larger firms. Additionally, the share of college educated workers increased in large firms that increased their import shares, indicating that firms upgrade their labor force when they become involved in international trade. Altogether, we find evidence of both a productivity effect and a supply effect, or workforce composition effect, in Denmark, a small open economy, as predicted by Grossman and Rossi-Hansberg (2008).
